TOPIC OUTLINE

Atomic Structure

Properties of Semiconductor

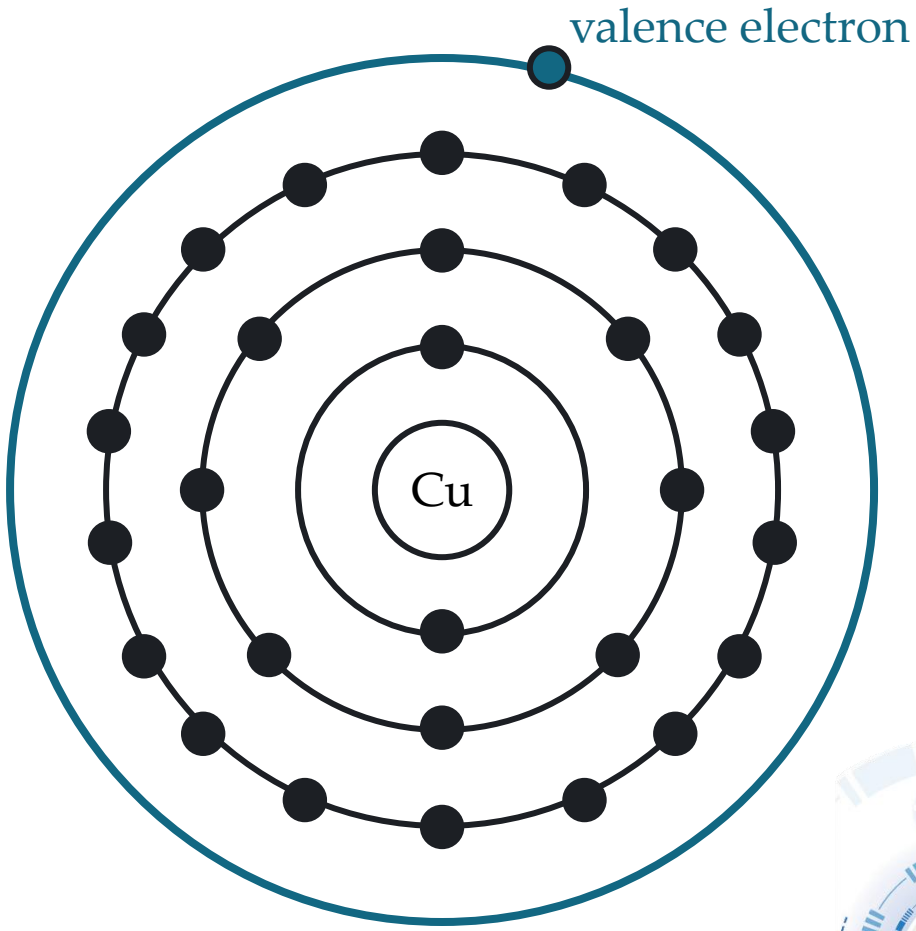
Two Types of Extrinsic Semiconductor

ATOMIC STRUCTURE

VALENCE ORBIT

The **valence orbit** (or valence shell) is the outermost electron shell of an atom. It contains the valence electron(s), which control the **electrical properties** of the atom.

Copper Atom



CONDUCTOR

Conductors are materials that allow the electric current to flow through them.

valence electrons

Less than 4 electrons

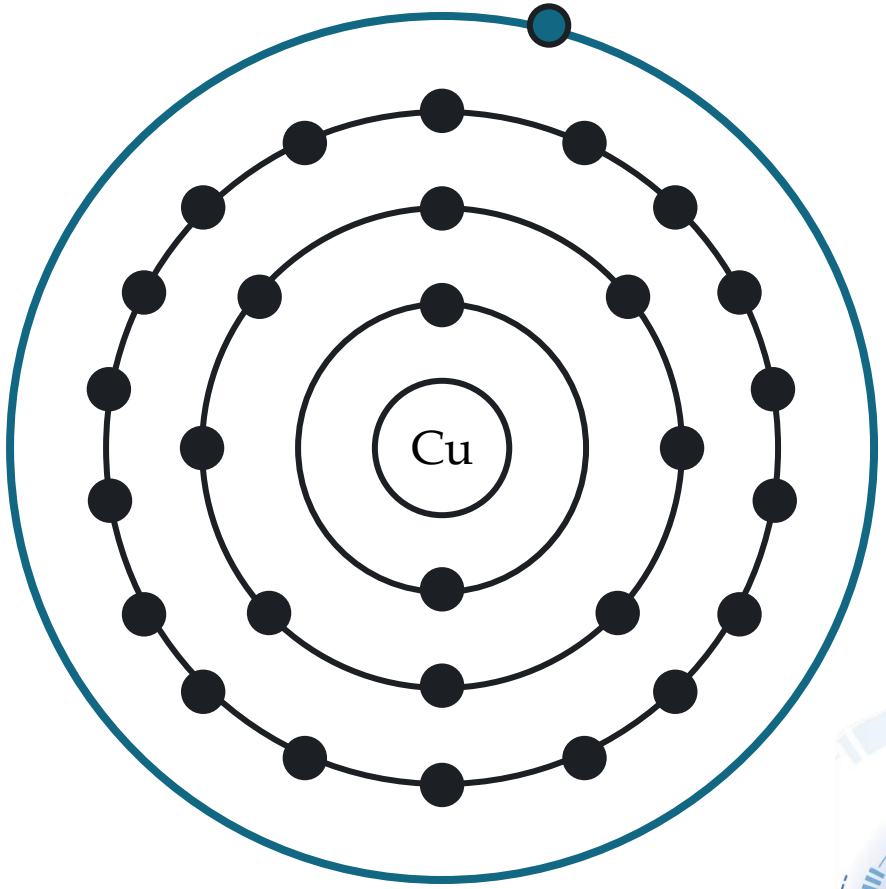
example

Copper

Silver

Gold

Copper Atom



INSULATOR

Insulators are materials that do not conduct electricity.

valence electrons

More than 4 electrons

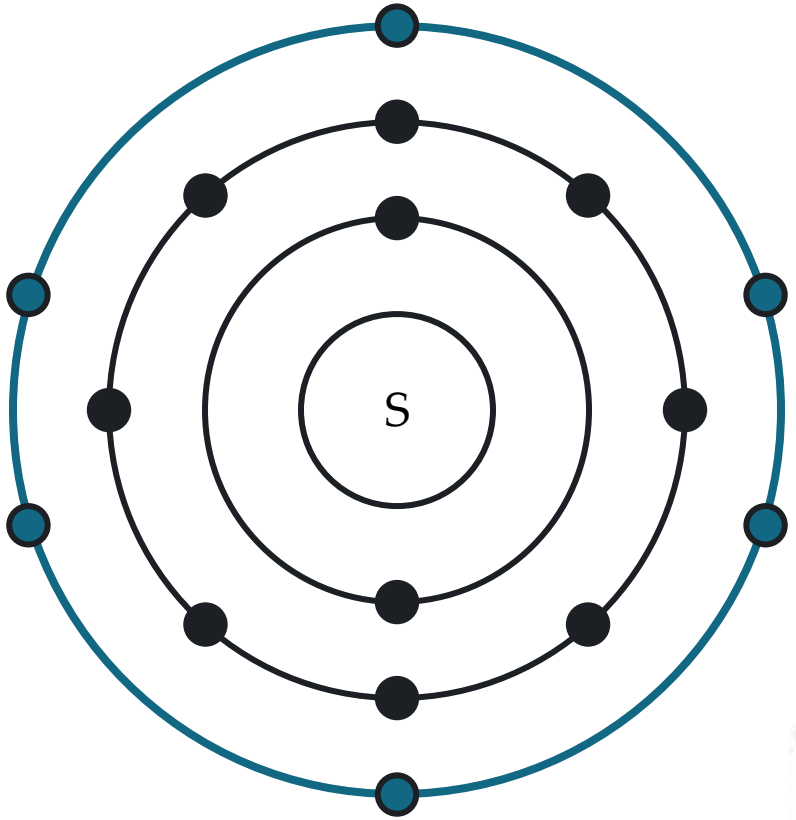
example

Rubber

Plastic

Sulfur

Sulfur Atom



SEMICONDUCTOR

Semiconductors are materials that have an electrical conductivity between that of a conductor and an insulator.

valence electrons

Exactly 4 electrons

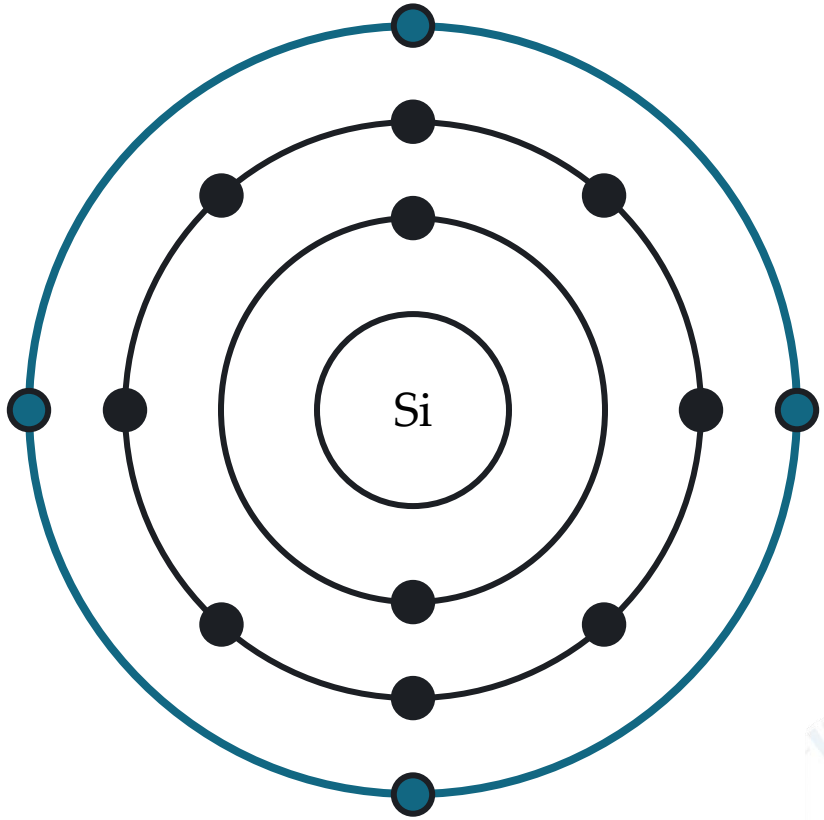
example

Silicon

Carbon

Germanium

Silicon Atom

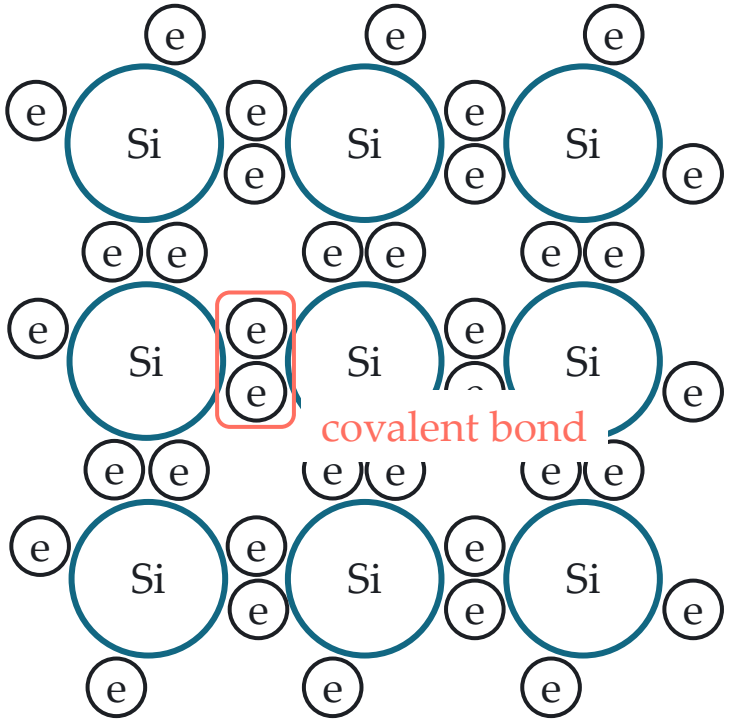


PROPERTIES OF SEMICONDUTOR

THE SILICON ATOM

A **valence saturation** occurs when an atom's outermost electron shell (valence orbit) reaches its maximum capacity of **8 electrons**.

Silicon Crystal

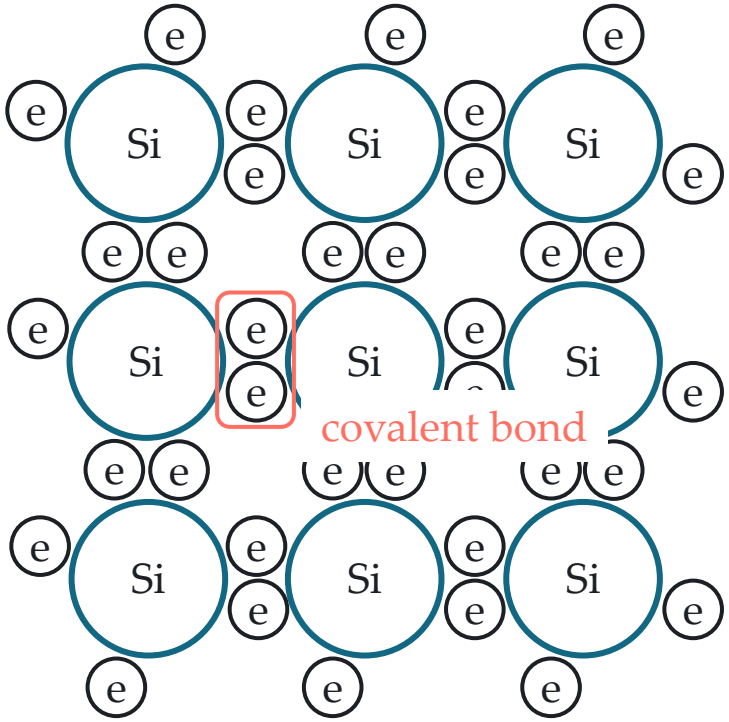


INTRINSIC SEMICONDUCTOR

An **intrinsic semiconductor** is a pure semiconductor.

At room temperature, it acts like an **insulator**.

Silicon Crystal



EXTRINSIC SEMICONDUCTOR

Doping is the process of **adding impurity atoms** to an intrinsic crystal to alter its electrical conductivity.

Group III Elements

B	Al	Ga	In
Boron	Aluminum	Gallium	Indium

Group V Elements

P	As	Sb
Phosphorus	Arsenic	Antimony

TWO TYPES OF EXTRINSIC SEMICONDUCTOR

TWO TYPES OF FLOW

Electron Flow

Electron flow is the movement of **free electrons** in a semiconductor (or conductor).

Hole Flow

Hole flow is the movement of "**empty spaces**" (holes) left behind when electrons jump in the valence band.

N-TYPE SEMICONDUCTOR

An **n-type** semiconductor is created by doping intrinsic semiconductor with a **pentavalent** impurity.

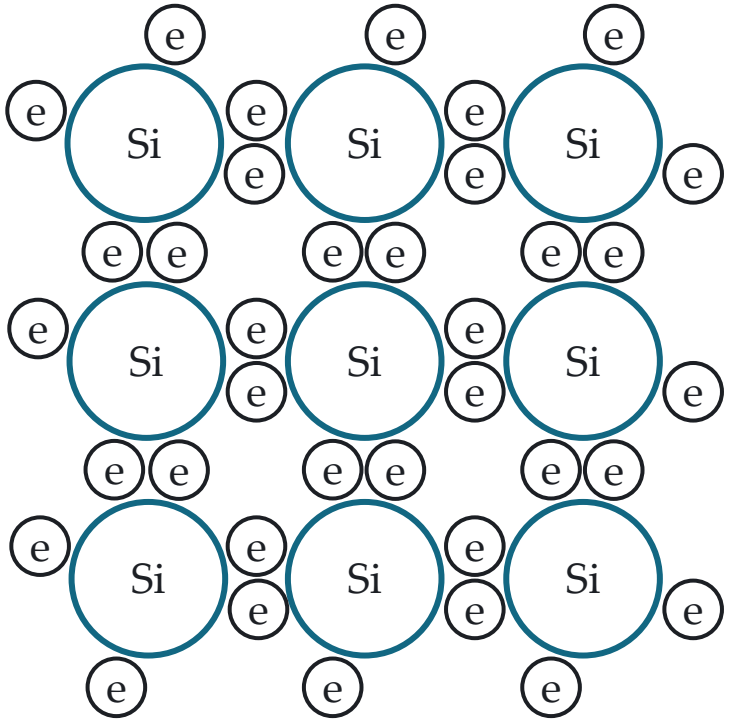
example

Arsenic (As)

Antimony (Sb)

Phosphorus (P)

Silicon Crystal



N-TYPE SEMICONDUCTOR

Doped with Phosphorus

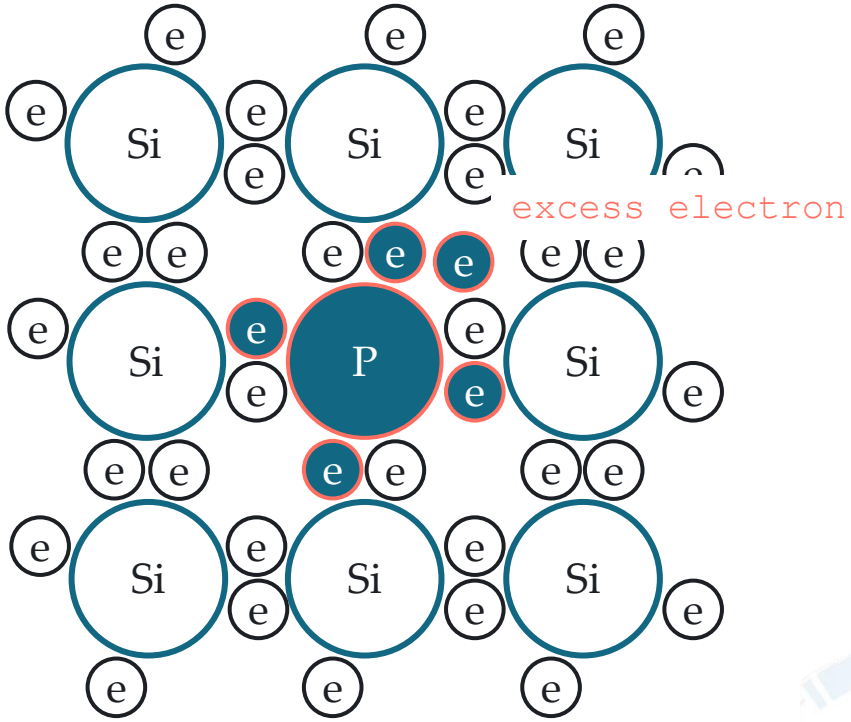
An **n-type** semiconductor is created by doping intrinsic semiconductor with a **pentavalent** impurity.

example

Arsenic (As)

Antimony (Sb)

Phosphorus (P)



N-TYPE SEMICONDUCTOR

Doped with Phosphorus

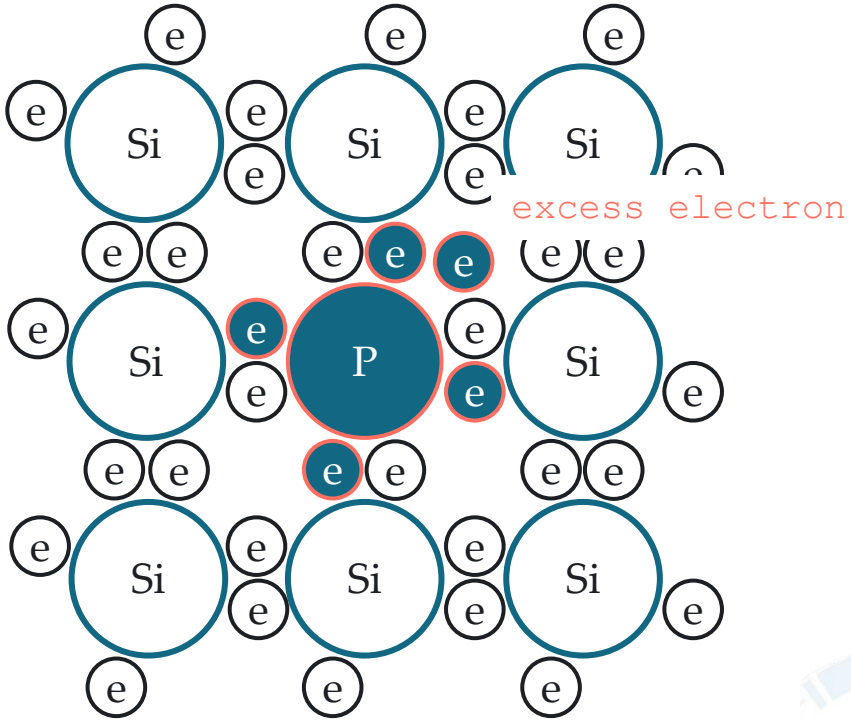
An **n-type** semiconductor is created by doping intrinsic semiconductor with a **pentavalent** impurity.

majority carriers

Electrons

minority carriers

Holes



P-TYPE SEMICONDUCTOR

A **p-type** semiconductor is created by doping intrinsic semiconductor with a **trivalent** impurity.

example

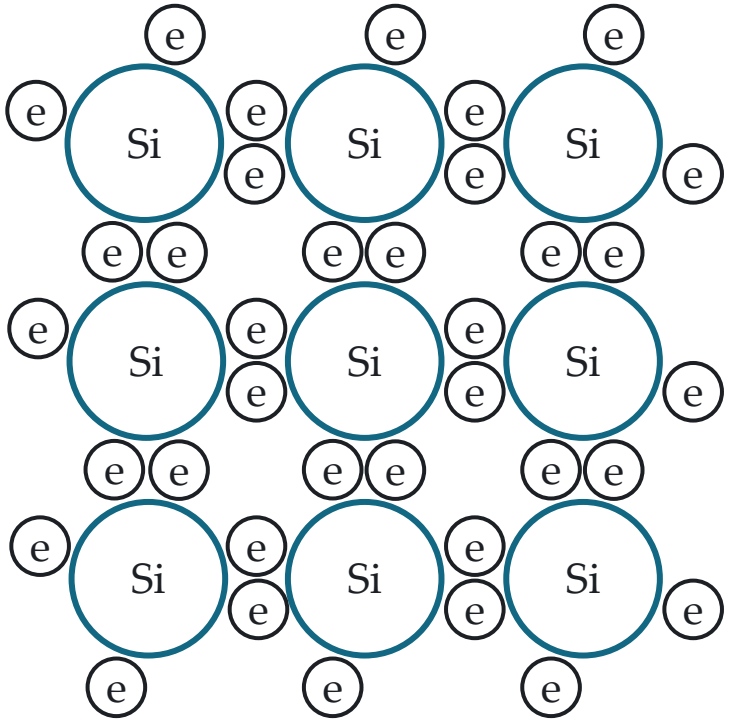
Aluminum (Al)

Boron (B)

Gallium (Ga)

Indium (In)

Silicon Crystal



P-TYPE SEMICONDUCTOR

A **p-type** semiconductor is created by doping intrinsic semiconductor with a **trivalent** impurity.

example

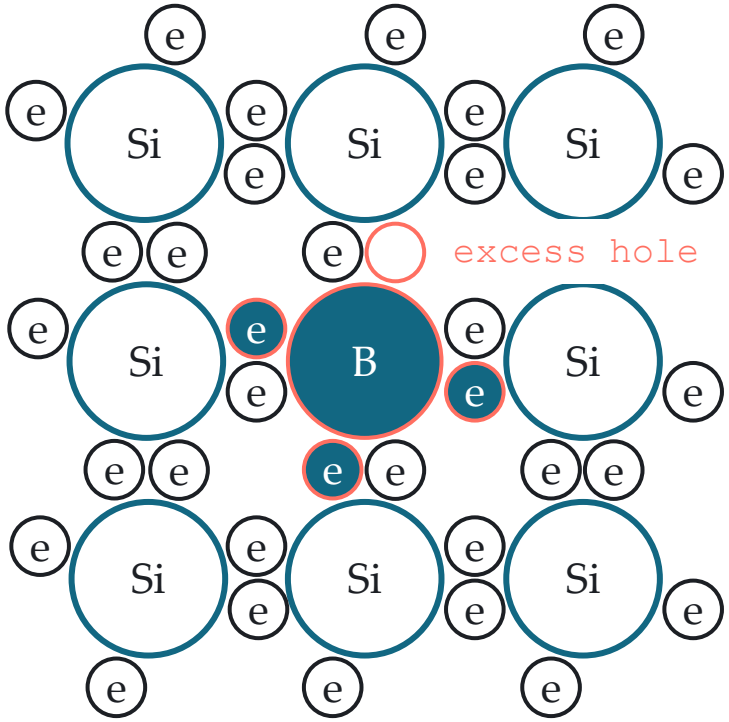
Aluminum (Al)

Boron (B)

Gallium (Ga)

Indium (In)

Doped with Boron



P-TYPE SEMICONDUCTOR

Doped with Boron

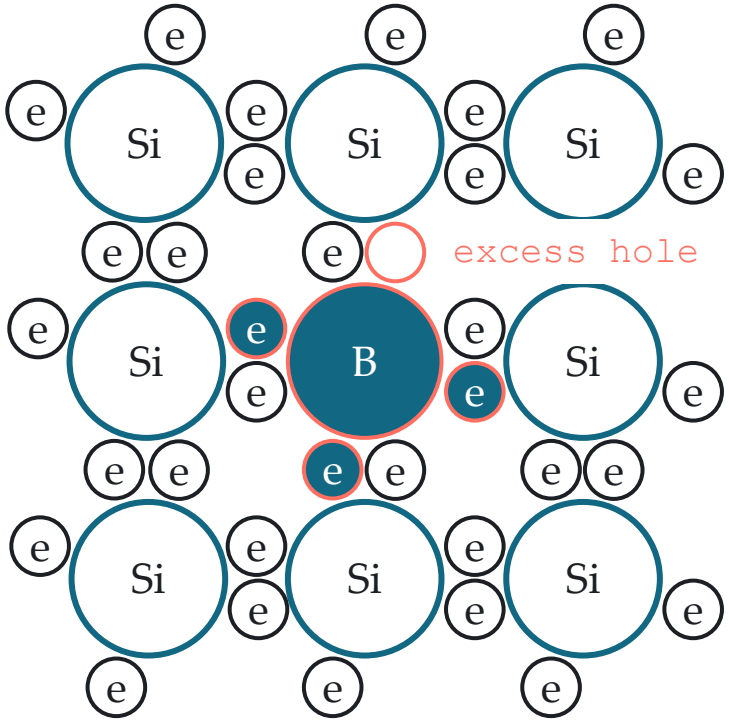
A **p-type** semiconductor is created by doping intrinsic semiconductor with a **trivalent** impurity.

majority carriers

Holes

minority carriers

Electrons



EXERCISE

A doped semiconductor has 10 billion silicon atoms and 15 million pentavalent atoms. If the ambient temperature is 25º C, how many free electrons and holes are there inside the semiconductor?

Solution

EXERCISE

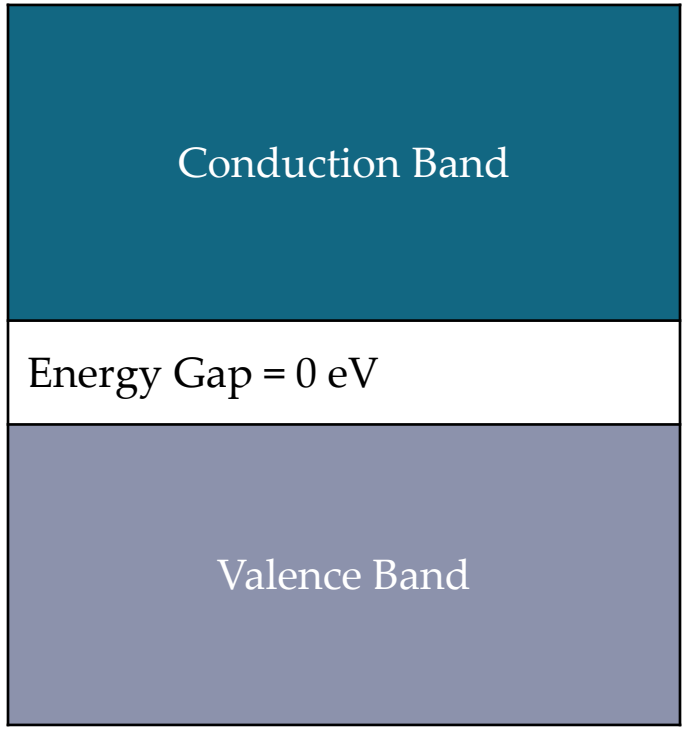
In reference to the previous example, if 5 million trivalent atoms are added instead of pentavalent atoms, how many holes are there inside the semiconductor?

Solution

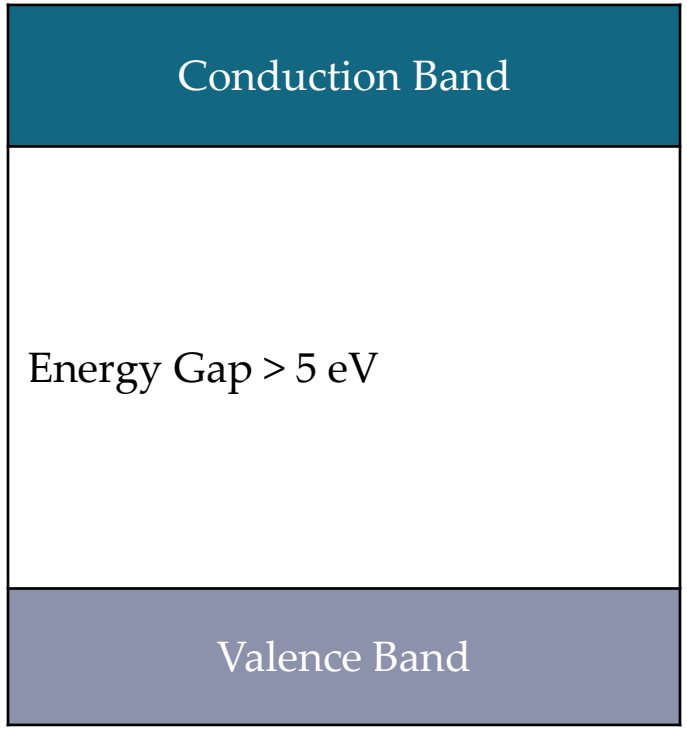
ENERGY LEVELS

Electronvolt (eV) is the energy needed to move one electron through a potential difference of 1 volt.

Conductor



Insulator



Semiconductor
